---

	<h2 style="text-align: center;">The Birth of Stars</h2>
<ul style="list-style-type: none"> <li>■ Nebula – a cloud of gas and dust in which a star's life cycle begins.</li> </ul>	

- composed of about 70% hydrogen 28% helium & 2% heavier elements
- particles in a nebula have a weak gravitational attraction for one another
- the smaller it gets, the faster it spins
- As it shrinks and spins it begins to flatten into a disk.

	<h2 style="text-align: center;">Protostar Stage</h2>
<ul style="list-style-type: none"> <li>■ The nebula begins to contract, the gravitational force increases, and it becomes a shrinking, spinning sphere</li> <li>■ Temperature, energy and pressure increases due to collisions</li> </ul>	

- collisions and pressure raise the temperature in the core of the protostar to over 10,000,000°C
- nuclear fusion begins
- protostar becomes a star

**Hydrogen Fusion Begins...  
*a star is born***

- Fusion is a nuclear reaction joining 2 hydrogen atoms to create helium. This begins the longest stage of a star's life...

---

---

---

---

---

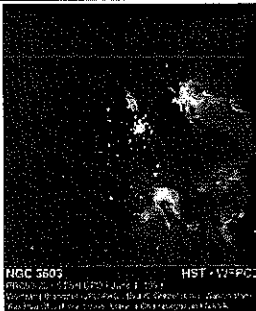

---

---

---

**Main-Sequence Stage**

- The longest stage in a star's life cycle.
- Hydrogen fusion is taking place.
- Stars are now "stable" because the force of gravity balances with the energy of FUSION.

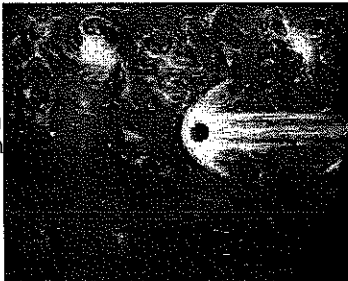

NCC 5509 HST-WFPC2  
ORION NEBULA (M42) June 1, 1994

• fusion releases enormous amounts of radiant energy.

1g of hydrogen, converted into helium releases enough energy to keep a 100W light bulb burning for 3000 years.

**Leaving the main sequence ...**

- When the Hydrogen runs out in the core...
- Helium fusion now occurs in core creating other elements.

• matter is pulled inward by the force of gravity

• star stays stable in size as long as it has hydrogen

### Giants and Supergiants

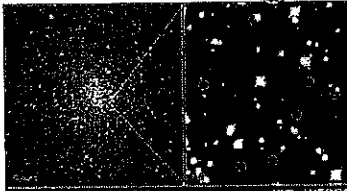

- The star begins to expand to a Giant or Supergiant.
- This depends on the MASS of the star.

- hydrogen fusion continues to take place in a shell surrounding the helium core.
- giants are 10 or more times bigger than the sun
- supergiants are at least 100 times bigger than the sun.

### Leaving the giant stage ...where to next??

- LOW MASS
- The star starts to shed its outer shell, exposing a **HOT, DENSE** core.
- Turns into a White Dwarf

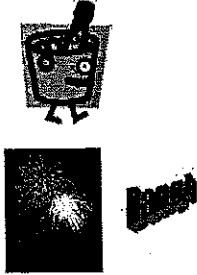

White Dwarf Stars in M4  
HST • WFPC2

- A white dwarf is the final stages of a star
- White dwarfs shine for billions of years before they cool completely.

### The end... for most stars

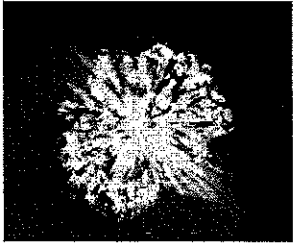

- White dwarfs will either:
  - Become black dwarfs after cooling
  - Or, become NOVAS if an explosion occurs during cooling.

- a nova may appear to be up to 1 million times brighter than the sun.
- a white dwarf may become a nova several times

**As for the big ones...  
the supergiants**

- High Mass
- Explode as SUPERNOVAS
- Produce heavier elements such as iron and magnesium

- Fusion continues until the core is almost entirely iron.
- nuclear fusion stops
- the iron core collapses
- outer part of star explodes

**After a Supernova**

- The core may contract into a small, but incredibly dense ball of neutrons – a neutron star

OR...

- If they are too massive to become neutron stars, they become

**BLACK HOLES**

- a spoonful of matter from a neutron star would weigh 100 million tons on the earth
- neutron stars rotate very rapidly
- neutron stars that emit 2 beams of radiation are called pulsars.
- black holes are found by the X-rays that are given off.
- astronomers speculate that massive black holes may be at the cores of many galaxies
